## Input into TACC

To: Gordon Dwane  
Gladstone Ports Corporation

Gordon,

Can I firstly apologise for the delay, I fully intended providing a fuller submission but have not been able to find the time.

### *Metals in sediment*

At the first TACC meeting I attended, I made comment about the risk of oversimplification of the character of sediments being moved around in the harbour particularly as it seems we have committed to ongoing disturbance of increasingly larger quantities of harbour sediments under the heading of “maintenance” dredging.

It stems from the fact that all sediment in the harbour contains appreciable levels of sulphides and the negligent attitude that this represents no risk when the concentrations are below an assumed threshold where the natural buffering capacity of the seawater prevents this from becoming “acidic”.

Where I intended to provide a more detailed expose of sediment metals contents, I now just provide a couple of tables from the WBDDP EIS. Almost every sample taken had detectable to serious levels of Arsenic, Chromium, Cobalt, Copper, Lead, Nickel and Vanadium. Its pervasiveness evidenced by the high proportion of “Number of Detects”.

Table 10 Statistical Summary and Compliance of 95% UCL to NAGD (2009) Screening Levels for Metals and Metalloids in Stage 1A

| Compound                            | Aluminium | Antimony | Arsenic | Cadmium | Chromium (III+VI) | Cobalt | Copper | Iron  | Lead  | Manganese | Mercury | Nickel | Selenium | Silver | Vanadium | Zinc   |
|-------------------------------------|-----------|----------|---------|---------|-------------------|--------|--------|-------|-------|-----------|---------|--------|----------|--------|----------|--------|
| Units                               | mg/kg     | mg/kg    | mg/kg   | mg/kg   | mg/kg             | mg/kg  | mg/kg  | mg/kg | mg/kg | mg/kg     | mg/kg   | mg/kg  | mg/kg    | mg/kg  | mg/kg    | mg/kg  |

It is not a one of for example limited to Stage 1A dredging but is also seen in the sediment characterisation of Stage 1B sediment.

Table 14 Statistical Summary and Compliance of 95% UCL to NAGD (2009) Screening Levels for Metals and Metalloids in Stage 1B

The significance of these environmentally dangerous metals has been dismissed as negligible, interpreting the levels as generally low concentrations, typically only a few tens of mg per kg of sediment and a fallacious assumption of non-mobility of the metals in "buffered" seawater conditions.

### Sulphides in the environment

The metals correlate with sulphur analyses suggesting they are present as metal sulphide, consistent with the anaerobic bacterial activity in the sediment particularly in mangroves and the sub-surface of the marine flood plains. While it is

accurate to point out that the presence of the metal sulphides are “natural” and reflect local geology, it is profoundly unnatural for these sulphides to be stirred up and suspended in the water column.

The sulphides are generally sequestered in stable sediment layers whereas mobile/saltating sediment is generally relatively free of sulphides. These biogenic sulphides are amorphous, cryptocrystalline in form and have very high surface area, making for very rapid reaction kinetics when exposed to chemically available oxygen. Even the dissolved oxygen in seawater will react with the metal sulphides, viz:

Note the formation of iron hydroxide, but of course all the other metal sulphide variants as clearly demonstrated to present in the harbour’s sediment can be substituted. Sea water typically contains 2 moles of dissolved oxygen; all that is required is 0.0064% sulphur as metal sulphide in the sediment to deliver 2 moles of metal into every cubic meter of slurred water. Even at levels well below the buffering capacity of seawater, these metal hydroxides are being generated and will report to the water column as stable colloids. These colloids remain suspended and will not gravity settle they are instead dealt with through biological activity from algae and bacteria such as schewanella implicated in the human health impacts of the dredging observed from Gladstone harbour.

### *Not all sediment is alike*

The relatively stable hydrodynamic conditions in the mangroves and marine flood plains, results in labile metals being sequestered into the sediments. It is this process after all that made it possible for our wonderful reef to exist. In contrast, in the active channels of the estuary, sediments are turned over frequently and are likely to be relatively low in sulphide content. Disturbing clean sediment would be relatively low impact as far as ASS is concerned. The artificial deep shipping channels on the other hand have been carved through historically stable sediment, high in sulphides. Certainly initially, the channels will be lined with high sulphide sediment. Every vessel movement through the channel will resuspend sulphides into the water column. Ultimately the sulphide content is likely to diminish as it is washed out and reacted with chemically available oxygen, but not before the walls of the channel stop slumping fresh sulphide sediment into the channel. This ongoing source of metal hydroxides into the water column will be spiked annually by maintenance dredging.

### *Skilfulness of experimental design*

How these dynamics I describe impact the harbour’s ecology are hard to quantify. We have learned that despite investing substantial resources, the authorities failed to make a definitive quantifiable link between ecological effects and dredging activities. Even though spatial and temporal evidence of turbidity plumes and dredging was abundantly clear and the strong correlation between metal levels and observed turbidity. The authorities failed to ascribe a cause to the human health impacts such as Schewanella infections, failed to explain unseasonal toxic algal blooms, failed to explain the pervasive red rashes on the bellies of almost ever fish species during the dredging, failed to identify the cause of turtle morbidity and associated metal toxication present in blood and organ samples of sick turtles. It flags a profound failure of the experimental design.

The skilfulness of an experiment is its ability to tell us more about our subject than we otherwise would have known. We waste out time and money if skilfulness is lacking.

I was asked the question, what I recommend is done to “monitor” the harbour?

My answer is that I am not the right person to give such advice as I am not specialised in this field. Even though I recognise failure of the WBDDP environmental management and monitoring processes to deliver a satisfactory outcome, I was not party to its design or implementation.

There are however some things to avoid and some guiding principles I feel should help.

- 1) Leadership – At the height of the ecological distress and the dredging campaign, the GPC leadership were publically and prominently denying the possibility of a causal link. It clearly was pre-emptive. Leadership failed to provide a culture of genuine learning.
- 2) Independence – The monitoring was carried out by an organisation with clear economic dependence on the proponent. Not to suggest any specific wrongdoing, it stands to reason that they would not want to bite the hand that feeds. The tone of supervisory comment of many of the reports deflect interpretation of causal links of water quality impact with dredging activities while frivolously linking observed variations to rainfall events.
- 3) Openness – Even though it was a condition of approval, data was denied the public. Reports were delayed and no operational data as to the exact timing of dredging was made available at all. What limited material could be accessed was showing substantial discrepancies. RTI requests for the data were refused, it took more than two years to get incomplete data and what data was provided was clearly incapable of resolving the water quality variation issues. Had the system been more open, the management system may have responded to feedback from the community and avoided such catastrophic failure of its monitoring program. It would be sooo nice if I could walk into a GPC office and converse with technical staff and look at data and share ideas and thoughts about all the material at hand rather than being sent from pillar to post and treated like a mushroom.
- 4) Inclusiveness – There was a stifling bureaucratic arrogance evident all the way from Mr Beattie's announcement of LNG on world heritage property to the Coordinator General's office gazumping of Curtis Island and its subsequent industrialisation. The profound marginalisation and misrepresentation of community input at all stages of the LNG rape of Curtis Island including the WBDDP was telling. For this I refer you to Risk = Hazard + Outrage [http://en.wikipedia.org/wiki/Outrage\\_factor](http://en.wikipedia.org/wiki/Outrage_factor). I strongly suggest GPC adopt some of Peter Sandman's advice in future programs.

Sincerely,

Jan Arens
